University, Ilara Mokin- Ondo State, Nigeria

ABSTRACT

Nigeria as a nation has suffered a lot when it comes to the availability of electricity. A clear comparison between this nation's electric power supply and other countries revealed the present incessant electric power supply in the country. The average power per capital (watts per person) in the United States is 1,377 Watts. In Canada, it is as high as 1,704 Watts per person and in South Africa; it is 445 Watts per person. The average power per capital in Australia is 1,112 Watts and in New Zealand it is 1,020 W per person. Whereas, the average power per capital (watts per person) in Nigeria is 14 W person. The power system structure is characterized with a lot of faults and outages. These electric power problem has destroyed the industrial processes in the country. As a result, unemployment has increased in the country. As at February, 2020, according to the Federal Government of Nigeria, the number of unemployed youths in the country is 23 million. Data from the International Transparency in the United State stated that there are 40 million unemployed youths in the country. This has increased crime rates among the youths. The country experience a high level of hardship, insecurity and socio-economic disorder as results. Therefore, there is an urgent need to solve this incessant supply of electric power in the country. Hence, a detail study of Akure_{132/33kV} substation Network of the Benin Electricity Distribution Company under which there are 84,264 customers was carried out. Reliability index of the distribution system were estimated. A model for establishing a hydro Electric Power Generating Plant was developed. Power Generation and Improvement techniques for the generation, transmission and distribution of electricity were achieved. The research work developed a model for establishing a hydro Electric Power Generating Plant and establish a monogram for increasing the value of power generation in a hydro generating station.

OBJECTIVES OF THE RESEARCH WORK

The objectives of the research work are

- I. to carry out detail study of Akure_{132/33kV} Substation Network of Benin Electricity Distribution Company (BEDC)

2. To measure the reliability index of the distribution system.
3. To develop a model for establishing a Hydro Electric Power Generating Plant.
4. To establish a monogram for increasing the value of power generation in the generating station.
5. To study the requirements for the establishment of an alternative Hydro Electric Power Generating plant

INTRODUCTION

The Federal Government of Nigeria promised to increase the power output by launching nine power plant projects in the country. But many of the power projects have been abandoned. After over 30 years, many of them were never completed. Even when all these projects are 100% completed, the total generating capacity in the country from the old power generating plants and these new projects will just be 8,274 MW. The average electricity consumed in watts per person in Nigeria will just be 45.97 Watts/person. Where-as, the average power per capital (watts per person) in the European Union with a population of 513,949,445 is 615 Watts/person, in the United States it is 1,377 Watts/person. In China, a country with population of 1,373,541,000, the average power per capital (watts per person) is 492 Watts/person, in South Africa, it is 445 Watts per person. The average power per capital in Australia is 1,112 Watts, in Russia it is 854 W per person and in Canada, it is as high as 1,704 Watts per person as shown in table 1.1

The lists of the said ongoing power projects in country are as follows:

1. 1700 Megawatts Hydro Power Plant Zungeru power plant in Niger state: This project was first conceived in 1982, but was abandoned due to lack of funds, corruption and dispute among the parties involved. Construction started again in 2016 and is expected to be completed by 2019. Though never completed.
2. 240 Mega Watts Afam Power Plant: Afam Power Plc is a thermal power plant located in the gas rich Rivers State. It is expected to be completed by December 2017. However, this power project has never been completed.

3. 40 Mega Watts Kashimbilla Hydro Power Plant Located in Taraba state: the construction of this 40 Mega Watts Kashimbilla power plant started in March 2017 and it is expected to be running by the end of the year 2017. Again, this Hydro Power Plant is not yet in operation
4. 215 Mega Watts Kaduna Power Plant: This power project contract in Kaduna state was awarded in 2009 and it was expected to be completed within 36 months. However, the project experienced great delay due to inadequate budgetary allocation and corruption among Nigerian Politicians. It was expected to be running before the end of year 2017. This power plant has not been completed up till today.
5. 450 Megawatts Azura Power Plant: Azura Thermal power station is a natural gas powered electricity generation plant with a proposed capacity of 1,500 megawatts, under construction in Edo state, Nigeria. It is an IPP project, with the first phase under construction. It is expected to be commissioned in 2018
6. 40 Mega Watts Gurara Power Plant in Kaduna state: it was estimated that the completion of the Gurara Hydro power plant would generate additional 30 megawatts. The project experience great delay due to inadequate budgetary allocation and corruption in the country.
7. 29 Mega Watts Dadin Kowa Hydro Power Plant Located in Gombe State: the construction of the Dadin Kowa plant is expected to be completed in November, 2017. Yet, this power plant is still incomplete.
8. 10 Mega Watts Katsina Wind Power Plant: The N4.4 billion Katsina Wind power plant project was awarded to a French company in 2010 and was scheduled for completion in 2012. However, the project has been stalled due to corruption and other several reasons. No completion date has been announced yet" AdeolaOpeyemi, 2016.

9. Mambilla Power Station: The Mambilla Power Station, one of Nigeria's biggest dam projects is a projected hydro power plant which will be connected to three dams across the Donga River in Taraba State, Nigeria, with a generating capacity of 3,050 megawatt.

Finally, the total generating capacity from these new 9 power plant projects, even when completed, is 4,774 MW. The present power generating capacity in Nigeria is estimated to be 6,803 megawatts, with average working capacity between 3,500 MW. Hence, the total generating capacity in the country will only become 11,577 MW (6,803 + 4,774). The total power generated in the country will only be 8,274 MW (3,500 + 4,774MW) and the average electricity consumed in watts per person in Nigeria will just be 45.97 Watts/person.

In order to provide solution to this incessant problem, a detail study of Akure132/33kV substation Network of the Benin Electricity Distribution Company under which there are 84,264 customers was carried out. Reliability index of the distribution system were estimated. A model for establishing a hydro Electric Power Generating Plant was developed. A monogram for increasing the value of power generation in the generating station was also developed. Power Generation and Improvement techniques for the generation, transmission and distribution of electricity were achieved.

Table 1.1: Electricity Energy Consumption in the World from the World Fact Book

| Rank | Country/Region | Electricity consumption (kW·h/yr) | Year of Data | Source | Population | As of | Average energy per capita (kWh per person per year) | Average power per capita (watts per person) |

The average power per capital/person in Nigeria is just 14 Watts. Therefore, there is need for a detail study of Akure 132/33kV substation Network of the Benin Electricity Distribution Company under which there are 84,264 customers. In this research work, reliability index of the distribution system were estimated and a model for establishing hydro Electric Power Generating Plant in the country was developed

POWER SYSTEM STRUCTURE IN NIGERIA

An electric power system consists of three major components: Generation, transmission and distribution (Kothari and Nagrath, 2008). The generating stations output voltage is usually between 11-25 kV. This will be increased by the step up transformers to 132 kV High Tension or 330 kV Extra High Voltage and transferred over long distance transmission lines. The transmission lines also connect one grid system to the other. Then all the loads in a particular network are connected to the transmission lines through the distribution transformers. For economic reasons, power plants are usually built close to the source of raw materials. This is because it is cheaper to transmit bulk electric energy over High Voltage (HV) of 132 kV or 330 kV Extra High Voltage (EHV) transmission lines than transport equivalent quantities of raw material like coal used in a thermal power plant over a long distance.

In case of Akure Power System, the first step down of voltage takes place at the transmission sub stations through 60 MVA, 132/33 kV injection transformers where the output transmission lines are 33 kV feeders. The next step down takes place at the 15 MVA, 33/11 kV substations. The outputs at the later substations are 11 kV feeders or primary distribution lines: a feeder in a distribution network is a circuit carrying power from a main substation to a primary or secondary substation such that the current loading is the same all along its length. The main criterion for the design of a feeder is its current carrying capacity. The last step down takes place at the secondary distribution sub-station which may be 200,300 or 500 kVA, 11/0.415 kV distribution transformer. These distribution transformers supply power to the domestic, industrial and commercial consumers through

the distribution lines called distributors as shown in figure 1.2. A distributor has a variable loading along its length. This is due to the service condition, tapping off at intervals by the individual consumers and the voltage variation at consumers terminals must be maintained within $\pm 5\%$ (Electricity Regulation of Nigeria, 2005)

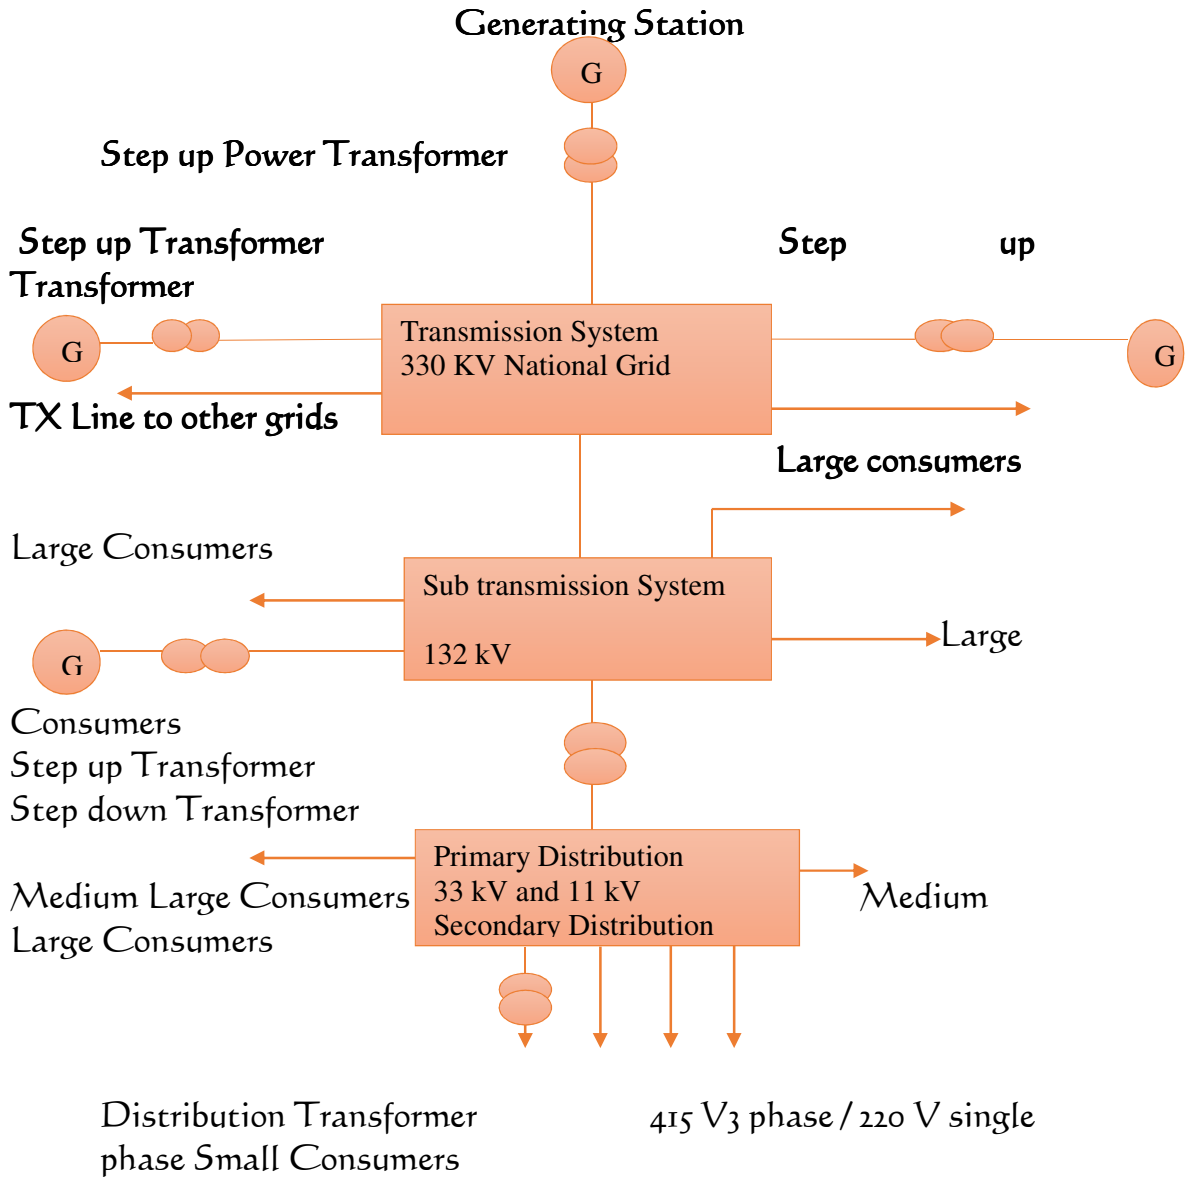

Fig 1.2 A typical power system network

CLASSIFICATION OF DISTRIBUTION SYSTEMS

Distribution system in Nigeria are classified according to the following factors:

Classification According to the Nature of Current.

A distribution system are classified according to the nature of current as:

- (a) D.C. distribution system and (b) A.C. distribution system

Classification According to the Types of Construction

This is the classification of the distribution system according to their type of construction. This include :(a) Overhead system: when the cable is overhead and (b) Underground system: when the cable is buried underground. The overhead system is generally employed for distribution in the country. This is because it is 5 to 10 times cheaper than the equivalent underground system.

Classification According To the Scheme of Connection

Distribution system are classified according to scheme of connection. This include: (a) Radial system (b) Ring main system and (c) Inter-connected system

CONNECTION SCHEMES OF DISTRIBUTION SYSTEM

The following distribution circuits are generally used in Akure distribution network:

I. Radial System

In this system, separate feeders radiate from a single substation and feed the distributors at only one end. All distribution of electrical energy is done by constant voltage system. Oshin O.A, Adanikin Ariyo, Fakorede Ebenezer, Joseph Ojotu, (2018) as shown figure below shows in figure 1.3

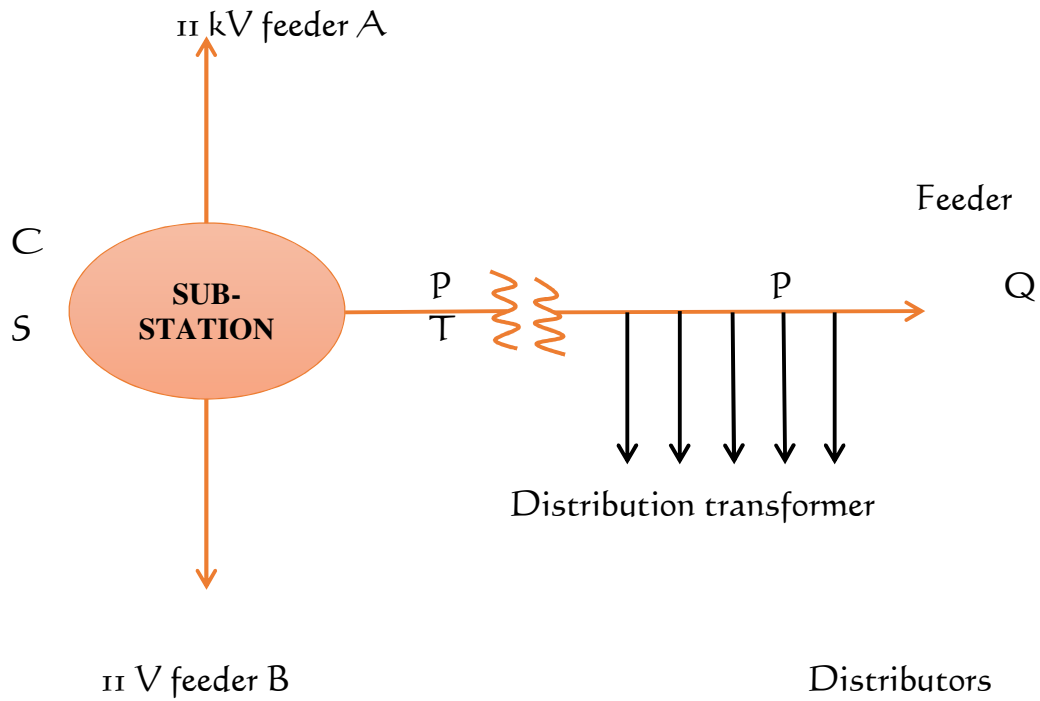

Figure 1.3: Single Line Diagram of a Radial System

RING MAIN SYSTEM

In this system, the primaries of distribution transformers form a loop. The loop circuit starts from the substation bus-bars, makes a loop through the state capital, and returns to the substation again as shown in figure 1.4: single line diagram of Ring Main System for A.C. distribution where a substation supplies electric power to the closed feeder LM, NO, PQ and RS. The distributors are tapped from different points M, O and Q of the feeder through the distribution transformer

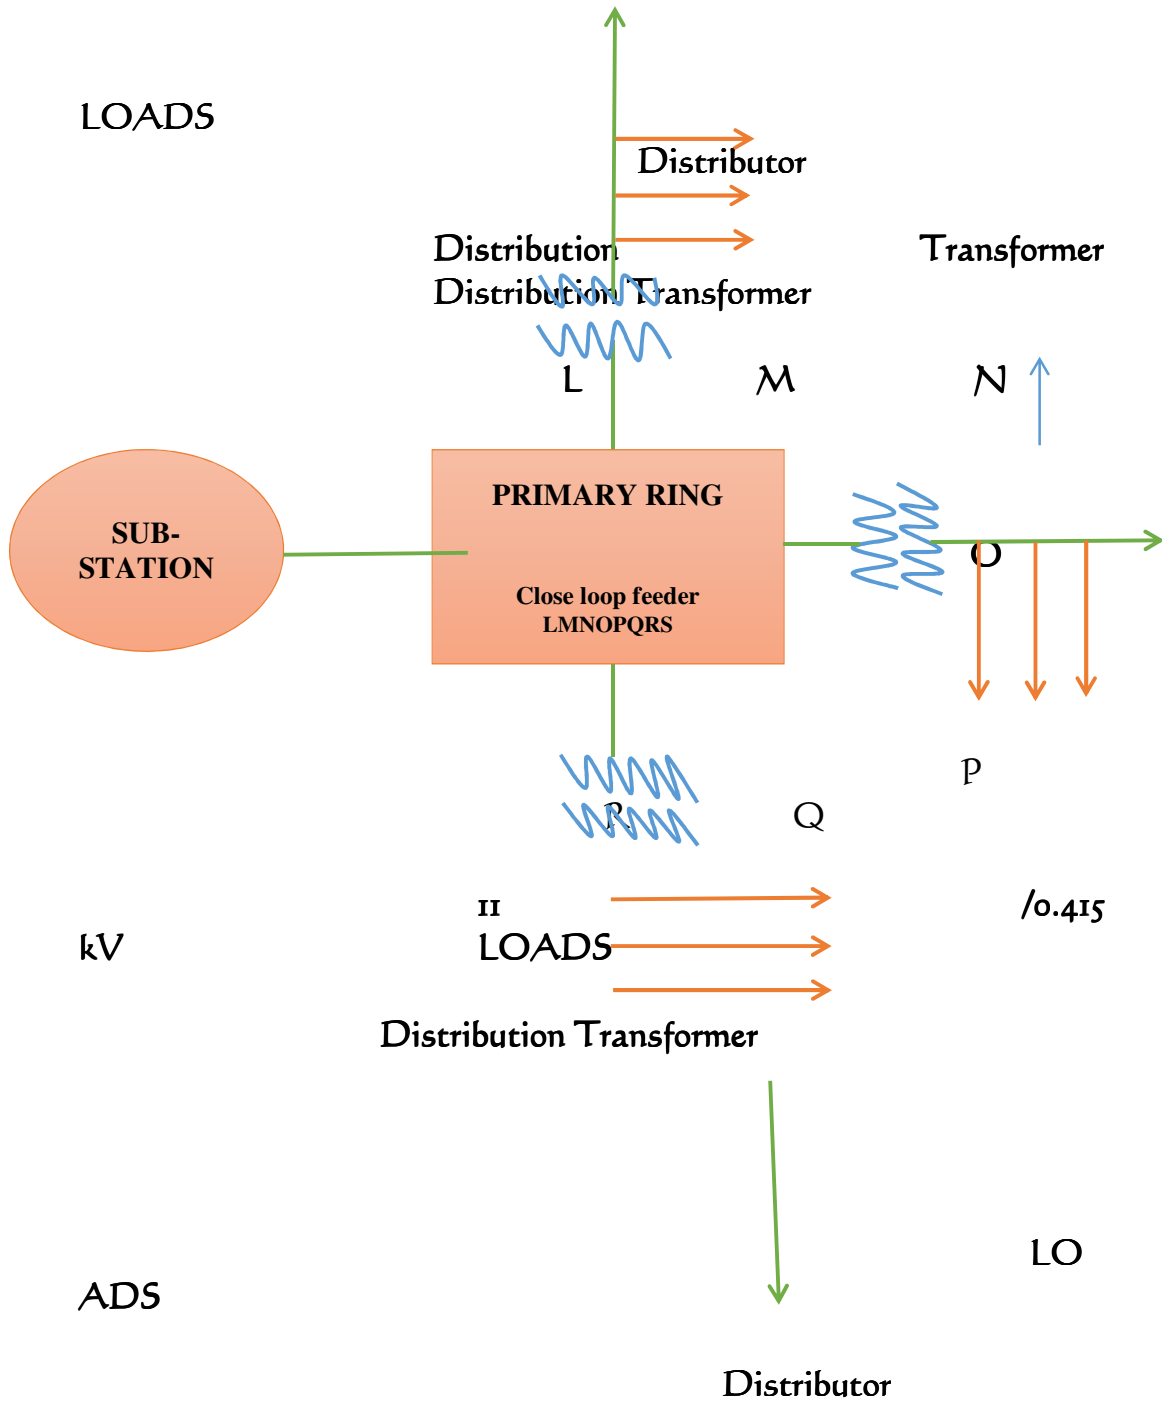

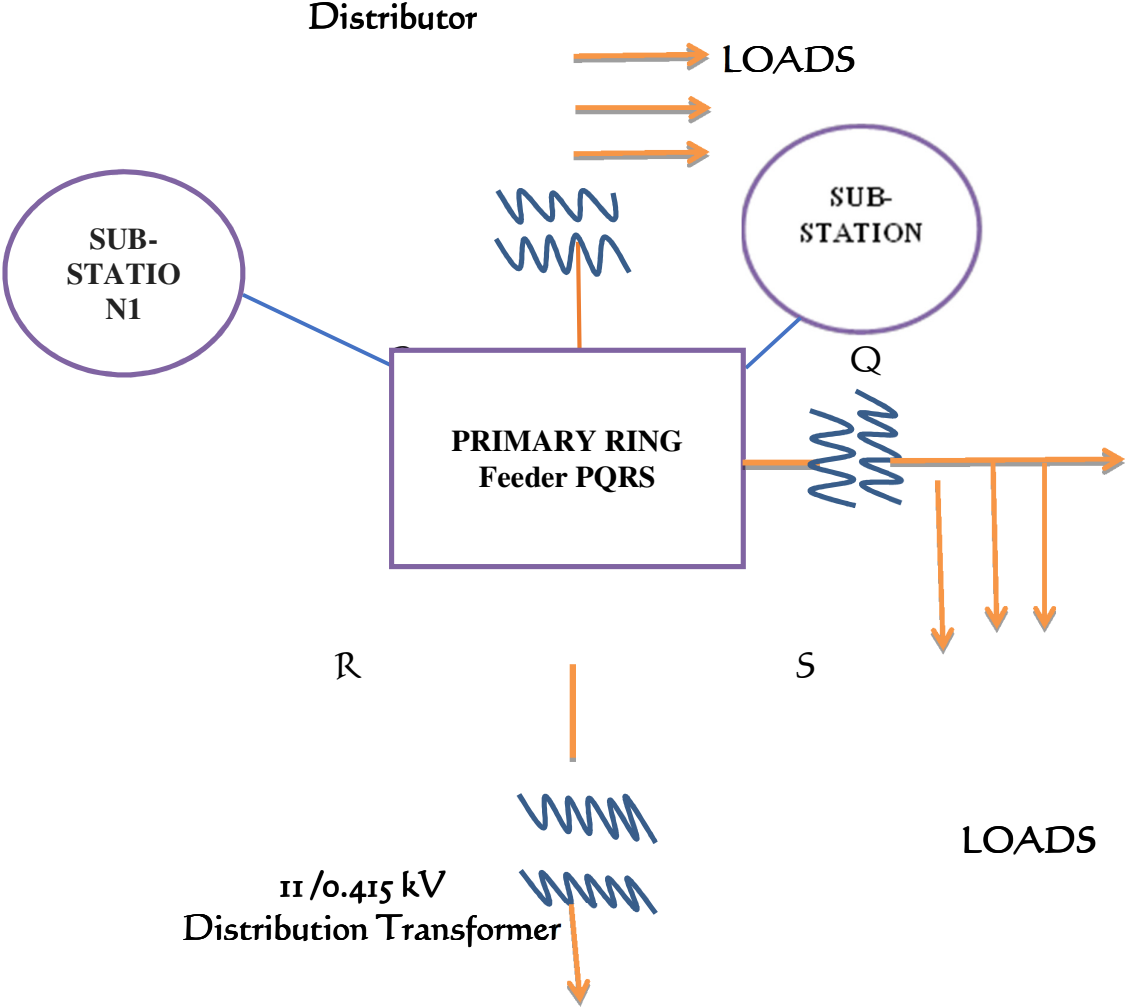

Figure 1.4 : Ring Main System

INTERCONNECTED SYSTEM

This is the feeder used when the feeder ring is energized by two or more than two generating stations or substations. Figure 1.5 shows the single line diagram of interconnected system where the closed feeder ring PQRS is supplied by two substations S_1 and S_2 at points P and Q respectively. Each feeder supplies a distribution transformer. The use of interconnected system provide reliable power supply than the first two methods of distribution systems. The distributors are connected to the transformers as shown below. This is recommended for the distribution of electricity in the country.

Development of a Model for the Establishment of a Hydro Electric Power
Generating Plant: Akure Distribution Network as a Case Study

Figure 1.5: Interconnected System

The interconnected system has the following advantages:

1. It increases the service reliability.
2. Any area fed from one generating station during peak load hours can be fed from the other generating station. This reduces reserve power capacity and increases efficiency of the system.

RESEARCH METHODOLOGY INTRODUCTION

The detail study of Akure132/33kV substation Network of the Benin Electricity Distribution Company under which there are 84,264 customers was carried out. Reliability index of the distribution system were estimated. A model for establishing a Hydro Electric Power Generating Plant was developed. A monogram for increasing the value of power generation in the generating station was also developed. Power Generation and Improvement techniques for the generation, transmission and distribution of electricity were also established.

Reliability index of the distribution network shows that power system of the study area were determined as follows.

System Average Interruption Frequency Index (SAIFI)

$$SAIFI = \frac{\text{Total number of sustained customers interruption in a year}}{\text{Total number of customer served}}$$

System Average Interruption Duration Index (SAIDI)

$$SAIDI = \frac{\text{Total duration of sustained interruption in a year}}{\text{Total number of customer served}}$$

Customer Average Interruption Frequency Index (CAIFI)

$$CAIFI = \frac{\text{Total number of annual customer interruptions}}{\text{Total number of customers affected}}$$

Customer Average Interruption Duration Index (CAIDI)

$$CAIDI = \frac{\text{Total Duration of Sustainable interruption in a year}}{\text{Total number of customer interruptions}}$$

Average Service Availability Index (ASAI)

$$ASAI = \frac{\text{Customer hours of available service}}{\text{customer hours demnded}}$$

Average Service Availability Index (ASUI)

$$ASUI = \frac{\text{Customer hours of unavailble/ service in a year}}{\text{customer hours demnded in a year}}$$

Onile, January, 2017,

Analysis of Ilesha Road Feeder

Improvement on power generation, transmission and distribution of electricity in the country is the only solution to the incessant electrical power supply which has grounded many activities and destroyed many industrial processes in the country. Otherwise, the present poor industrial systems, high unemployment rates, crimes, suffering and untimely deaths in the country will continue to increase. This is because industrial development, employment, production of good and services of any country is directly proportional to the electrical energy consumed by the citizens of that country. Also, more efforts should be given to fault clearing systems and improvement in the reliability of the system. The Federal Government of Nigeria needs to genuinely privatize only the distribution aspect of electricity in Nigeria as this is the normal practice in the developed countries. The present privatization of the electrical generating stations in the country is a wrong method of privatization. Instead, individual or organization who is/are interested in electric power generation should establish his/her generating plant and supply excess power generated to the national grid.

Ondo Road Feeder Results

Mean time between failure stands at an average of 491.46 hours between year 2010 and 2017. That means there will be an average of one failure in every 491.46 hours. Mean down time along the feeder is 195.6 hours. This result shows that the supply of electricity along the feeder is characterize with high number of failures. Availability of electric power along feeder is 73.34 %. But the reliability of the feeder is 1.83904×10^{-7} i.e. 0.00000018 %

$$\begin{aligned}
 \text{SAIFI} &= 0.002734 \text{ failure/customer} & \text{SAIDI} &= \\
 & 0.27556 \text{ hour/customer} & & \\
 \text{CAIFI} &= 0.005088 \text{ interruption/consumer} & \text{CAIDI} &= 100.8 \\
 \text{ASAI} &= 0.827397 \text{ or } 82.7397\% & \text{ASUI} &= 0.172603 \text{ or } \\
 & 0.172603\% & &
 \end{aligned}$$

Ijapo Feeder Results

The failure rate of the feeder is 0.0017706 failure/ hour. Mean time between failure stands at an average of 564.78022 hours between year 2010 and 2017. The Mean down time along the feeder within this period is 205.32967 hours. This result shows that the supply of electricity along the feeder is also characterize with high number of failures. Availability of electric power along the feeder is 73.337614%; while the reliability of the feeder stands at an average of 1.84×10^{-7}

| | | | |
|--|--|-------|---|
| SAIFI = 0.002432 failure/customer | | SAIDI | = |
| 0.306445 hour/customer | | | |
| CAIFI = 0.003902 interruption/consumer | | CAIDI | = |
| 126 hours | | | |
| ASAI = 0.827397 or 82.7397 % | | ASUI | = |
| 0.172603 or 17.2603 % | | | |

Oba Ile Feeder Results

The failure rate of the feeder between year 2010 and 2017 is 0.001855034 failure/ hour. Mean time between failure stands at an average of 539.07 hours. Mean down time along the feeder is 198.61 hours. This result shows that the supply of electricity along the feeder is characterize with high number of failures. Availability of electric power along Oba Ile feeder is 73.08%, but the reliability of the power system: 8.778×10^{-8} is a very poor one.

| | | | |
|--|--|-------|---|
| SAIFI = 0.002138275 failure/customer | | SAIDI | = |
| 0.323236 hour/customer | | | |
| CAIFI = 0.002439 interruption/consumer | | CAIDI | = |
| 151.1667 hours | | | |
| ASAI = 0.792922 or 79.2922 % | | ASUI | = |
| 0.207078 or 20.7078 % | | | |

Alagbaka Feeder Results

The failure rate of the feeder between year 2010 and 2017 is 0.0018089 failure/ hour. Mean time between failure stands at an average of 552.83 hours. Mean down time along the feeder is 208.913 hours. The result shows that the supply of electricity along the

feeder is characterize with high number of failures. Availability of electric power along the feeder is 72.574% whereas the reliability along the feeder is approximately equal to zero i.e. 1.315×10^{-7}

$$\begin{aligned} \text{SAIFI} &= 0.002866 \text{ failure/customer} & \text{SAIDI} &= \\ & 0.355374 \text{ hour/customer} & & \\ \text{CAIFI} &= 0.004276 \text{ interruption/consumer} & \text{CAIDI} &= 124 \\ & \text{hours} & & \\ \text{ASAI} &= 0.801826 \text{ or } 80.1826 \% & \text{ASUI} &= \\ & 0.198174 \text{ or } 19.8174 \% & & \end{aligned}$$

Oke Eda Feeder Results

The failure rate of the feeder between year 2010 and 2017 is 0.00185 failure/ hour. Mean time between failure stands at an average of 540.46875 hours. Mean down time along the feeder is 189.53 hours. This result shows that the supply of electricity along the feeder is characterize with high number of failures. Availability of electric power along the feeder is 74.0368%, while the reliability is 9.1542×10^{-8}

$$\begin{aligned} \text{SAIFI} &= 0.0023015 \text{ failure/customer} & \text{SAIDI} &= \\ & 0.31339 \text{ hour/customer} & & \\ \text{CAIFI} &= 0.00406 \text{ interruption/consumer} & \text{CAIDI} &= \\ & 136.167 \text{ hours} & & \\ \text{ASAI} &= 0.813470 \text{ or } 81.3470 \% & \text{ASUI} &= \\ & 0.18653 \text{ or } 18.653 \% & & \end{aligned}$$

Oyemekun Feeder Result

The failure rate of the feeder between year 2010 and 2017 is 0.00216577 failure/ hour. Mean time between failure stands at an average of 461.728972 Hours. Mean down time along the feeder is 193.224 hours. This result shows that the supply of electricity along the feeder is characterize with high number of failures. Availability of electric power along the feeder is 70.498 %, while the reliability is 5.772×10^{-9}

$$\begin{aligned} \text{SAIFI} &= 0.002328 \text{ failure/customer} & \text{SAIDI} &= \\ & 0.374736 \text{ hour/customer} & & \\ \text{CAIFI} &= 0.003563 \text{ interruption/consumer} & \text{CAIDI} &= 161 \text{ hours} \\ \text{ASAI} &= 0.797831 \text{ or } 79.7831 \% & \text{ASUI} &= 0.202169 \text{ or } \\ & 20.2169 \% & & \end{aligned}$$

Ilesha Road Feeder Results

The failure rate of the feeder between year 2010 and 2017 is 0.001857 failure/hour. Mean time between failure stands at an average of 538.554 hours. Mean down time along the feeder is 223.185 hours. This result shows that the supply of electricity along the feeder is characterized with high number of failures. Availability of electric power along the feeder is 70.7%, while the reliability of the feeder is approximately equal to zero i.e. 8.642×10^{-8}

$$\begin{aligned} \text{SAIFI} &= 0.00249 \text{ failure/customer} & \text{SAIDI} &= \\ & 0.33749 \text{ hour/customer} & & \\ \text{CAIFI} &= 0.00416 \text{ interruption/consumer} & \text{CAIDI} &= \\ & 135.462 & & \\ \text{ASAI} &= 0.798973 \text{ or } 79.8973 \% & \text{ASUI} &= \\ & 0.20103 \text{ or } 20.103 \% & & \end{aligned}$$

Isikan Feeder Results

The failure rate of the feeder between year 2010 and 2017 is 0.001882279 failure/hour. Mean time between failure stands at an average of 531.2708 hours during the eight years. Mean down time along the feeder is 198.7292 hours. Again, this results show that the supply of electricity along the feeder is characterized with high number of failures. Availability of electric power along the feeder is 72.7768%, but the reliability of the feeder is 6.914×10^{-8}

$$\begin{aligned} \text{SAIFI} &= 0.003577 \text{ failure/customer} & \text{SAIDI} &= \\ & 0.392801 \text{ hour/customer} & & \\ \text{CAIFI} &= 0.004462 \text{ interruption/consumer} & \text{CAIDI} &= \\ & 109.8125 & & \\ \text{ASAI} &= 0.79943 \text{ or } 79.943 \% & \text{ASUI} &= 0.20057 \text{ or } \\ & 20.057 & & \end{aligned}$$

MODELLING OF AN HYDRO ELECTRIC POWER GENERATING PLANT

Modelling Of an Hydro Electric Power Generating Plant

In order to provide solution to the present incessant electrical power supply in the country, this research work established a model for the

establishment of Hydro Electric Power Generating Plant was developed. Hydro-electric power stations require the utilization of energy in falling water for the rotation of water turbine and the rotor situated in an alternator for the generation of electricity. They are generally located in hilly areas where dams can be built conveniently and large water reservoirs can be obtained. In a hydro-electric power station, water head is created by constructing a dam across a river or lake and from the dam, water is led to a water turbine. The water turbine captures the energy in the falling water and changes the hydraulic energy (i.e. product of head and flow of water) into mechanical energy at the turbine shaft. V.K Metha and Rohit Metha, (2010), Oshin O.A, Adanikin Ariyo, Abiodun Onile, (2017). The turbine drives the alternator which converts mechanical energy into electrical energy as shown in figure 3.1

Figure 3.1 : Hydro Electric Power Plant

The power generated in a hydro-electric power station is given in the equation below

$$\text{Power Generated} = \ell \int \left[\frac{(h_s - h - h_1) g A}{L} dt \right] + q_c \quad g [h_s - h - h_1]$$

Where

- a. L = incompressible conduit length of the penstock L
- b. A = cross sectional area of the penstock in m^3
- c. ℓ = density of water
- d. q = discharge rate in $m^3/\text{sec} = \int \left[\frac{(h_s - h - h_1) g A}{L} dt \right] + q_c$
- e. h_s = static head of water column in meters
- f. h_1 = loss in height because of friction in the penstock in meters
- g. h = head of turbine admission in meters
- h. T_w = water time constant or water starting time

The rate of change of the discharge rate with respect to time is equal to $\frac{dq}{dt}$

Where system operating discharge rate = $\frac{dq}{dt} = \frac{(h_s - h - h_1) g A}{L}$

Flow rate $q = \int \left[\left(\frac{(h_s - h - h_1) g A}{L} dt \right) + q_c \right]$

Power Generated = $\ell q g [h_s - h - h_1]$
 Then, Power Generated = $\ell \left\{ \int \left[\left(\frac{(h_s - h - h_1) g A}{L} dt \right) \right] + q_c \right\} g [h_s - h - h_1]$

In a Hydro-Electric Power Plant, the value of $\int \left[\left(\frac{(h_s - h - h_1) g A}{L} dt \right) \right]$ is negligible

Hence, Power Generated = $\ell q_c g [h_s - h - h_1]$

CONCLUSION

The incessant electric power supply problems which has destroyed the existence of processing and production industries in Nigeria is a pointer to the fact that there is great need a great need for fault evaluation and reliability studies of electric power system. This power problem resulted to incessant planned, forced and unplanned outages. In addition, it has resulted to erratic and unreliable supply of electricity in the country. As said earlier, it has grounded many activities and has destroyed many industrial processes. It has reduced productivity and has increased unemployment rate in the country to over 40million (this figure is over 70% of Nigerian youths). It has led many of the youths in the country to crime. It has led to the deaths of many innocent people in the country. This research work therefore analyzed the problems facing Akure Distribution System Network. The research work also evaluated the occurrence of faults and outages in the Distribution Network Area for a period of 8 years (2010 -2017).The research work also established a model for the establishment of Hydro Electric Power Generating Plant in the country. When the results of this research work are utilized, it will be easy to established efficient Hydro Electric

Power Plant in the country. The efficiency and the efficiency of the modelled power plant can be increased using the established model.

RECOMMENDATION

In order to meet the increasing demand for electricity in Akure Distribution Network and in other parts of the country, the following recommendations have been made.

1. Though the total installed generating capacity in the country is 6,367MW, the country is only able to generate 3,500 MW because most facilities have been poorly managed and the reliability of the generating, transmission and distribution system been very low due to high failure rates of equipment, large energy losses, corruption among government officials and poor protection of power system. Hence, Increase in generated power is necessary because the Energy Commission of Nigeria has shown that electricity demand in the country will rise from the present 9,437MW to 15,730 MW by the year 2015. Therefore additional Power Stations should be established in the country.
2. There is a need to install more transformers and distribution lines close to the consumers, this will reduce losses along the 132kV, 33kV and 11kV lines and increase efficiency.
3. Decentralization of the energy system in Nigeria should be treated with serious attention and cordial treatment.
4. Solar Photovoltaic System should be installed in every house hold in the country.
5. Also, New Distribution transformer Sub Stations should be installed, this will reduce excess load on distribution transformers. As a result, transformers breakdown, constant failures and outages which have become very frequent in the country will be reduced.
6. There should be provision for adequate Planning and Construction of more transmission and distribution lines in order to improve the performance of power system.
7. Maintenance of existing generating plant, transmission line and distribution systems should be improved.
8. The grounding system of all distribution transformers must be adequate. The lightning Arresters must be sensitive. All D-Fuses

- and G & P Fuses must work according to the required specifications. Otherwise such device must be replaced
9. The transmission and distribution aspects of electricity in Nigeria, excluding the generation aspect, should be privatized. In exactly the same way as it is being done in the developed countries. That means the Federal Government should withdraw the sales of Egbin Thermal Power Plant, Afam Power plc, Kainji Hydro-Electric plc, Sapele Power plc, Shiroro Hydro-Electric plc and Ughelli Power plc and return them back to the Federal Government in the Country.
 10. The present privatization of the electrical generating stations in the country is a wrong method of privatization. Instead, individual or organization who is/are interested in electric power generation should establish his/her generating plant and supply excess power generated to the national grid.
